

SECTION C

11 (**short**) The titles of ten children's books and their average reader ratings are stored in the Python data structure:

```
Kidsbooks = {"Peppa Pig": 4.4, "Peter Rabbit": 4.2, "Gruffalo": 4.9,
             "Gingerbread Man": 1.1, "Goldilocks": 4.1, "Bedtime Stories":
             3.5, "Snow White": 3.9, "My Little Dog": 4.3, "Animals": 2.0,
             "Three Little Pigs": 3.7}
```

(a) Describe which data structure is used above, and give an example of a task that can be completed efficiently using this data structure. [2]

(b) An inexperienced developer has written the following fragment of Python to implement a feature. Describe the purpose of this code fragment, and give the output of the print statement.

```
v = list(Kidsbooks.values())
k = list(Kidsbooks.keys())
r = 3
result = []
for i in range(r):
    max_v = max(v)
    # return the index in list v at which max_v appears
    index_max_v = v.index(max_v)
    result.append(k[index_max_v])
    k.remove(k[index_max_v])
    v.remove(max_v)
print(result) [6]
```

(c) The parameter `r` is now set to `len(Kidsbooks)`. Describe what the new feature does. [2]
